25						
26	A novel, s	trictly anaerobic, thermophilic, sulfur-reducing bacterium designated PH1209 <sup>T</sup> , was				
27	isolated fro	m an East Pacific Rise hydrothermal vent (13°N) sample and subjected to a polyphasic				
28	taxonomic a	analysis. The cells were Gram-negative motile rods (approximately 1.60 x 0.40 $\mu$ m) with a				
29	single polar	flagellum. Strain PH1209 <sup>T</sup> grew at temperatures between 33 and 65°C (optimum 60°C),				
30	from pH 5.	0 to 8.0 (optimum 6.0-6.5) and between 2 and 4% (w/v) NaCl (optimum 3%). Cells grew				

chemolithoautotrophically with  $H_2$  as an energy source, S° as an electron acceptor and CO<sub>2</sub> as a carbon source. Alternatively, strain PH1209<sup>T</sup> was able to use peptone and yeast extract as carbon sources. The G+C content of the genomic DNA was 35 mol%.

Phylogenetic analyses based on 16S rRNA gene sequencing showed that strain PH1209<sup>T</sup> fell within the order *Nautiliales*, in the class *Epsilonproteobacteria*. Comparative 16S rRNA gene sequence analysis indicated that strain PH1209<sup>T</sup> belonged to the genus *Nautilia*, and shared, respectively, 97.2 and 98.7% 16S rRNA gene sequence identity with *Nautilia lithotrophica* and *Nautilia profundicola*. It is proposed, from the polyphasic evidence, that the strain should be placed into a novel species, *Nautilia abyssi* sp. nov. The type strain is PH1209<sup>T</sup> (= DSM 21157<sup>T</sup> = JCM 15390<sup>T</sup>).

40

41 Epsilonproteobacteria are widely distributed in marine and terrestrial ecosystems (Campbell et al., 2006). 42 They are particularly common and abundant in 30-70°C areas of deep sea hydrothermal vents, as indicated 43 by their prevalence in the clone libraries (Polz & Cavanaugh, 1995; Longnecker & Reysenbach, 2001; Lopez-Garcia, 2002; Alain et al., 2004), the results of fluorescence in situ hybridization (Moussard et al., 44 2006) and the isolation of several representatives (Alain et al., 2002; Miroshnichenko et al., 2002; Inagaki et 45 al., 2003; Takai et al., 2003, 2005, 2006; Voordeckers et al., 2005). Within this singular ecosystem, 46 Epsilonproteobacteria are retrieved in various habitats, thriving (i) as free-living organisms on chimney 47 structures, within vent plumes and in sediments, (ii) as epi- or endosymbionts of hydrothermal invertebrates, 48 or (iii) embedded in mats on the surfaces of chimney rocks or animals. Cultured isolates from deep-sea vents 49 50 are all mesophilic to thermophilic chemolithoautotrophs coupling the oxidation of hydrogen or sulfur compounds to the reduction of nitrate, sulfur compounds or oxygen (Takai et al., 2003; Campbell et al., 51 2006). Because of their abundance and metabolic abilities, Epsilonproteobacteria are likely to be key 52 players of the carbon, sulfur and nitrogen biogeochemical cycling at deep-sea vents. 53

Two orders are currently described within the class *Epsilonproteobacteria* Garrity *et al.* 2006 (Validation List n°107, Garrity *et al.*, 2005), namely the *Nautiliales* (Miroshnichenko *et al.*, 2004) and the *Campylobacterales* Garrity *et al.* 2006 (Validation List n°107, Garrity *et al.*, 2005). The order *Nautiliales* comprises the genera *Nautilia* (Miroshnichenko *et al.*, 2002), *Caminibacter* (Alain *et al.*, 2002) and *Lebetimonas* (Takai *et al.*, 2005) which are exclusively composed of thermophilic strains isolated from deep-sea hydrothermal vents and which have been found in association with invertebrates or with chimney edifices. At present, the genus *Nautilia* is composed of two species, *Nautilia lithotrophica* (Miroshnichenko *et al.*, 2002) and *Nautilia profundicola* (Smith *et al.*, 2008). Both strains are strictly anaerobic sulfurreducing mixotrophs able to grow on hydrogen and carbon dioxide, or alternatively on formate.

- In this study, a novel marine bacterium belonging to the genus *Nautilia* is described. Based on the results of
   a polyphasic taxonomic analysis, the strain PH1209<sup>T</sup> represents a novel species, *Nautilia abyssi* sp. nov.
- 65

In April-May 2002, during the PHARE oceanographic cruise, fragments of active hydrothermal chimney 66 rocks covered with colonies of the tubeworm polychaete Alvinella spp. were collected from 2620m depth at 67 the Elsa vent field, on the East Pacific Rise 13°N (12°48'N, 103°56'W). Sample collection, subsampling and 68 69 storage procedures were as described elsewhere (Alain et al., 2004). One subsample collected on the Ph01 chimney was used to inoculate series of media, including KA22 medium (Alain et al., 2002), and incubated 70 at 60°C under a gas phase of H<sub>2</sub>/CO<sub>2</sub> (80/20; 200 kPa). After 24h incubation, dense populations of short, 71 rod-shaped, motile cells were observed and purified by repeated dilution to extinction series. One isolate, 72 referenced as strain PH1209<sup>T</sup>, is described in this publication. Purity of this isolate was confirmed routinely 73 by microscopic examination and by repeated partial sequencing of the 16S rRNA gene using several 74 primers. Stock cultures were stored at -80°C in KA22 medium supplemented with 5% (v/v) DMSO. 75

76

Morphological characteristics of the cells were determined by light microscopy (Olympus CX40) and by scanning electron microscopy (FEI Quanta 200). Cells of strain PH1209<sup>T</sup> were Gram-negative, straight rods of 1.05-2.21  $\mu$ m in length (mean 1.63 $\mu$ m  $\pm$  0.34, n=11) and 0.30-0.51  $\mu$ m in width (mean 0.39  $\pm$  0.05, n=11) in the mid-exponential phase of growth (see Supplementary Fig. S1 in IJSEM online). They occurred mainly singly and were highly motile by a polar flagellum (Fig. S1A). Division was by constriction (Fig. S1B). Formation of spores was never observed.

83

The physiological characterization of the novel isolate was carried out in a basal medium referenced as "NPKsalts" and containing (per liter): 0.33 g NH<sub>4</sub>Cl, 0.33 g KCl, 0.33 g CaCl<sub>2</sub>.2H<sub>2</sub>O, 0.33 g MgCl<sub>2</sub>.6H<sub>2</sub>O, 25 g NaCl, 1.0 g NaNO<sub>3</sub>, 1.95 g MES buffer (Sigma) and 1 mg resazurin (Sigma). Its pH was adjusted to

6.0. Once prepared, this medium was autoclaved and then cooled to room temperature under a stream of O<sub>2</sub>-87 free N<sub>2</sub> gas. Concentrated anaerobic filter-sterilized solutions of vitamins and trace elements were added to 88 the medium after autoclaving. Then, just before inoculation, Na<sub>2</sub>S.9H<sub>2</sub>O, KH<sub>2</sub>PO<sub>4</sub> and elemental sulfur were 89 provided from sterile stocks, to final concentrations of 0.04% (w/v), 20 mM and 1.2% (w/v), respectively. 90 91 Unless stated otherwise, the experiments were carried out anaerobically, under a gas phase of  $H_2/CO_2$ (80/20; 200 kPa), and incubation were done in the dark and under agitation. Growth was routinely 92 monitored by direct cell counting using a modified Thoma chamber (depth 10  $\mu$ m), or by counting after 93 94 fixation with 1% (v/v) glutaraldehyde and storage at  $-20^{\circ}$ C. Growth rates were calculated using linear 95 regression analysis of four to nine points along the logarithmic portions of the resulting growth curves. The determination of the temperature range for growth was tested over the range 30-80°C (i.e. 30, 33, 37, 45, 50, 96 97 55, 60, 65, 70, 75, 80°C). No growth was observed at 30°C, 70°C and above. The novel isolate grew from 33 to 65°C, with an optimum growth rate at 60°C (see Supplementary Fig. S2A in IJSEM online). The pH 98 range for growth was tested at 60°C in basal medium buffered and adjusted to the required initial pH as 99 described elsewhere (Alain et al., 2002). Growth was observed from pH 5.0 to pH 8.0, the optimum being 100 around pH 6.0-6.5 (Fig. S2B). No growth was observed at pH 4.0 and pH 8.5. Salt tolerance was tested at 101 60°C in NPKsalts medium prepared with various concentrations of NaCl (0, 0.5, 1, 2, 3, 4, 5, 6, 8 and 10% 102 w/v). Growth was observed at salt concentrations ranging from 2 to 4% (w/v) NaCl, the optimum salinity 103 being around 3% (Fig. S2C). No growth was observed at 1 and 5% (w/v) NaCl. Under optimal growth 104 conditions, the generation time of strain PH1209<sup>T</sup> was around 120 minutes. 105

106

Strain PH1209<sup>T</sup> was a strictly anaerobic, chemolithoautotrophic bacterium that used sulfur, hydrogen and 107 108 carbon dioxide as respective primary electron acceptor, electron donor and carbon source. Its ability to use alternative electron acceptors was tested by adding colloidal sulfur (Sigma Aldrich) (5 g  $l^{-1}$ ), L-cystine (12 g 109 1<sup>-1</sup>), sulfite (1 mM), thiosulfate (20 mM), sulfate (20 mM), nitrate (10 mM), nitrite (1 mM) and oxygen (1% 110 111 v/v) to nitrate and sulfur-depleted media, under an atmosphere of H<sub>2</sub>/CO<sub>2</sub> (80/20; 200 kPa). Quantitative 112 determination of hydrogen sulfide was as described elsewhere (Cord-Ruwisch, 1985). The novel isolate was 113 found to grow with elemental sulfur and colloidal sulfur, with concomitant production of H<sub>2</sub>S, but did not grow when L-cystine, sulfite, thiosulfate, sulfate, nitrate, nitrite and oxygen were used as electron acceptors. 114

To examine possible carbon sources other than CO<sub>2</sub>, a variety of organic carbon sources were tested in the 115 presence of sulfur, under an atmosphere of H<sub>2</sub> 100% (200 kPa). Formate (10 mM), acetate (10 mM), 116 butyrate (10 mM), propionate (10 mM), methanol (0.5% v/v), pyruvate (10 mM), lactate (0.5% v/v), 117 fumarate (10 mM), glucose (10 mM), peptone (2 g  $l^{-1}$ ) and yeast extract (2 g  $l^{-1}$ ) were tested as potential 118 119 substrates. Heterotrophic growth (with concomitant H<sub>2</sub>S production) was observed exclusively with yeast extract and peptone and was probably the result of the decarboxylation of amino acids. The growth rates 120 with yeast extract and peptone were in the same order of magnitude than the one measured with carbon 121 122 dioxide as carbon source. To test for the capability of the strain to use electron donors other than molecular hydrogen, the strain was cultivated under a gas phase of N<sub>2</sub>/CO<sub>2</sub> (80/20, 200 kPa) in the presence of formate 123 (20 mM), acetate (20 mM), methanol 0.5% (v/v) and yeast extract (2 g  $l^{-1}$ ), and with sulfur as a terminal 124 125 electron acceptor. No growth was observed with the alternative energy sources, indicating that strain PH1209<sup>T</sup> was a strict hydrogen-oxidizer. The nitrogen sources for growth were also examined in a nitrogen-126 depleted medium. The novel isolate was found to grow on organic and inorganic nitrogen sources. 127 Significant growth was observed when NH<sub>4</sub>Cl (20 mM), glutamate (10 mM), yeast extract (0.2 g  $1^{-1}$ ), 128 tryptone (0.2 g  $l^{-1}$ ), gelatin (0.05% v/v) and urea (0.05% v/v) were provided as sole nitrogen source. 129

130

Antibiotic resistance was tested in the presence of a variety of antibiotics from different chemical nature and 131 with different targets and mechanisms. The resistance to vancomycin, streptomycin, chloramphenicol, 132 133 kanamycin, rifampicin, penicillin, ampicillin and tetracycline was investigated at concentrations of 10, 25, 50 and 100  $\mu$ g ml<sup>-1</sup>. When the antibiotic was diluted in ethanol (chloramphenicol) or DMSO (rifampicin), 134 the same volume of solvent was added to control cultures. All antibiotics were added aseptically before 135 inoculation and the cultures were incubated at 60°C for one week. Strain PH1209<sup>T</sup> was found to be sensitive 136 to vancomycin, streptomycin, chloramphenicol, penicillin, ampicillin and tetracycline, all at 10  $\mu$ g ml<sup>-1</sup>. It 137 grew in the presence of 10  $\mu$ g ml<sup>-1</sup> rifampicin and 25  $\mu$ g ml<sup>-1</sup> kanamycin, but was sensitive to higher 138 139 concentrations of these two antibiotics.

140

141 The genomic DNA G+C content was determined, by the Identification Service of the DSMZ (Deutsche 142 Sammlung von Mikroorganismen und Zellkulturen GmbH, Braunschweig, Germany), by HPLC analysis of deoxyribonucleosides as described by Mesbah *et al.* (1989). The G+C content of strain PH1209<sup>T</sup> was 35 mol%.

145

146 The almost complete 16S rRNA gene (1369 bp) of the strain was double-strand sequenced, as described 147 elsewhere (Alain et al., 2002). This sequence was compared to those in available databases by use of the BLAST program (Altschul et al., 1990) and then aligned to its nearest neighbours using the CLUSTALX 148 program (Thompson et al., 1997). Alignments were refined manually using the SEAVIEW program (Galtier 149 150 et al., 1996). Distance matrixes were calculated with the Lasergene 6 version software. Phylogenetic trees 151 constructed by the PHYLIP (PHYlogeny Inference Package) version 3.63 software were (http://evolution.genetics.washington.edu/phylip/getme.html) on the basis of evolutionary distance 152 (neighbour-joining method with Jukes and Cantor corrections) (Saitou and Nei, 1987) and maximum 153 likelihood (Felsenstein, 1981). The robustness of the inferred topologies was assessed by bootstrap analyses 154 based on 1000 bootstrap resamplings for the neighbour-joining and 100 replications for the maximum 155 likelihood method (Felsenstein, 1985). Comparison of the 16S rRNA gene sequence with sequences of 156 Bacteria indicated that the novel isolate belonged to the class Epsilonproteobacteria Garrity et al. 2006 157 (Validation List n°107, Garrity et al., 2005) and more especially to the order Nautiliales (Miroshnichenko et 158 al., 2004). Within this lineage that is composed exclusively of taxa from deep-sea hydrothermal vents, the 159 novel isolate was found to be most closely related to a group of moderately thermophilic sulfur reducers, all 160 isolated from the EPR 13°N like PH1209<sup>T</sup> (Fig. 1). The novel isolate shared 98.7% 16S rRNA gene 161 sequence identity with *Nautilia profundicola* strain AmH<sup>T</sup> (Smith *et al.*, 2008), 97.2% 16S rRNA gene 162 sequence identity with Nautilia lithotrophica strain 525<sup>T</sup> (Miroshnichenko et al., 2002) and 97.4% 16S 163 rRNA gene sequence identity with strain Ex-18.2, a third isolate not formerly described (Campbell et al., 164 165 2001). These three closest relatives were all isolated from tubes of the worm Alvinella pompejana and 166 belonged to the genus Nautilia. Otherwise, the novel isolate was most distantly related to members of the genera Lebetimonas and Caminibacter, sharing 91.9% to 93.2% 16S rRNA gene sequence identity with 167 representative species of these genera (Table 1). Based on the sequence similarity and phylogenetic 168 169 analyses, the novel isolate could be assigned to the genus Nautilia. The level of 16S rDNA sequence dissimilarity with *N. profundicola* and *N. lithotrophica* suggests that the novel isolate belongs to a novel
species (Stackebrandt and Ebers, 2006).

172

The phenotypic and genotypic properties of the novel isolate described herein generally met the minimal 173 characteristics described for the order Nautiliales (Miroshnichenko et al., 2004). Indeed, strain PH1209<sup>T</sup> is a 174 marine thermophilic sulfur-reducing bacterium growing chemolithoautrophically from  $H_2$  oxidation. It 175 unambiguously branches with other *Nautiliales*. Nevertheless, strain PH1209<sup>T</sup> can be easily distinguished 176 177 from other *Nautiliales* species in terms of a number of phylogenetic, genotypic and physiological features. 178 These distinctive criteria are detailed in Table 1. In brief, in addition to the phylogenetic distance, the novel taxon differs from its closest relatives by its temperature, NaCl and pH ranges for growth. Its generation 179 180 time under optimal growth condition is also slightly different from the ones of its relatives. Furthermore, differences in the utilization profiles of carbon sources, electron donors and electron acceptors are also 181 observed. In contrast to its congeners N. lithotrophica and N. profundicola which are able to use formate as 182 energy and carbon source, the novel isolate is unable. Finally, another distinctive criterion is the DNA G+C 183 content. In conclusion, in view of all the above-mentioned distinctive features, we propose that the isolate 184 PH1209<sup>T</sup> should be assigned as the type strain of a novel species, for which the name *Nautilia abyssi* sp. 185 nov. is proposed. 186

187

#### 188 Description of Nautilia abyssi sp. nov.

189 Nautilia abyssi (a.bys'si. L. gen. n. abyssi, of an abyss, of the great deep).

190 Cells are Gram-negative motile rods, approximately 1.6 µm in length and 0.4 µm in width, with a single polar flagellum. 191 Optimal growth occurs at 60°C, with a growth range from 33 to 65°C. The pH and NaCl ranges are 5.0-8.0 (optimum 192 6.0-6.5) and 2-4% (w/v) (optimum, 3% w/v NaCl), respectively. Growth occurs under strictly anaerobic conditions 193 using  $H_2$  as an electron donor, elemental sulfur (or colloidal sulfur) as a terminal electron acceptor and  $CO_2$  as a carbon 194 source. Yeast extract and peptone can be used as alternative carbon sources, but formate, acetate, methanol, lactate, 195 propionate, fumarate, malate, citrate, pyruvate, glucose and glycogen can not. The following are not utilized as electron 196 acceptors: L-cystine, thiosulfate, sulfate, sulfate, nitrate, nitrite, oxygen. The following are not used as electron donors: formate, acetate, methanol and yeast extract. Sensitive to 10  $\mu$ g ml<sup>-1</sup> of the following antibiotics: vancomycin, 197

streptomycin, chloramphenicol, penicillin, ampicillin, tetracycline; sensitive to 25  $\mu$ g ml<sup>-1</sup> rifampicin and 50  $\mu$ g ml<sup>-1</sup> kanamycin. Genomic DNA G+C content of the type strain PH1209<sup>T</sup> is 35 mol%.

The type strain, PH1209<sup>T</sup> (DSM 21157<sup>T</sup>, JCM 15390<sup>T</sup>) was isolated from the walls of an active deep-sea hydrothermal chimney colonized with alvinellid worms, on the East Pacific Rise (103°56'W, 12°48'N). It is also available under request at the "Souchothèque de Bretagne" (catalogue LMBE) culture collection (http://www.ifremer.fr/souchotheque/).

203

### 204 ACKNOWLEDGEMENTS

We acknowledge Prof. J. P. Euzéby for support in the Latin etymologies of the species name. We thank the captain and crew of the NO *L'Atalante*, the pilots and support crew of the ROV *Victor* and N. Le Bris, Chief Scientist for helping us to collect deep-sea hydrothermal vent samples during the PHARE oceanographic cruise. We are grateful to the anonymous reviewers for their constructive comments about the manuscript. This work was financially supported by the Région Bretagne and the joined research unit UMR6197, linking the Université de Bretagne Occidentale to the Ifremer and the Centre National de la Recherche Scientifique.

## 290 **TABLES and FIGURES**

291 292

Fig. 1. Phylogenetic tree based on 16S rRNA gene sequences of strain PH1209<sup>T</sup> and representative 293 members of related genera within the class Epsilonproteobacteria. Sequence data of reference strains 294 were obtained from the GenBank/EMBL and/or RDP databases. Two species from the 295 296 Gammaproteobacteria were chosen as outgroups. Accession numbers are indicated in parentheses. The topology shown corresponds to an unrooted tree obtained by the maximum likelihood algorithm, established 297 using the PHYLIP package. Bootstrap values (from 100 replicates) are indicated at the branch nodes. The 298 positioning of the novel isolate was confirmed by the neighbour-joining method. The scale bar indicates 2 nt 299 substitutions per 100 nt. 300

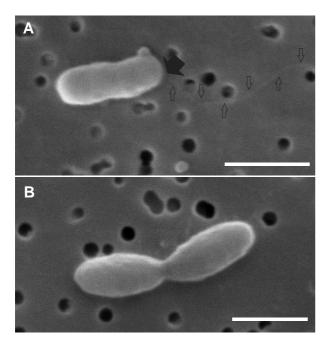

301

## 302 Table 1. Characteristics differentiating strain PH1209<sup>T</sup> from related species of the order *Nautiliales*.

Species: 1, Nautilia abyssi PH1209<sup>T</sup> (this study); 2, Nautilia profundicola AmH<sup>T</sup> (Smith et al., 2008); 3,
Nautilia lithotrophica 525<sup>T</sup> (Miroshnichenko et al., 2002); 4, Caminibacter hydrogeniphilus AM1116<sup>T</sup>
(Alain et al., 2002); 5, Caminibacter profundus CR<sup>T</sup> (Miroshnichenko et al., 2004); 6, Caminibacter
mediatlanticus TB-2<sup>T</sup> (Voordeckers et al., 2005); 7, Lebetimonas acidiphila Pd55<sup>T</sup> (Takai et al., 2005).

- 307 Legend: +, positive; -, negative; w, weak growth; ND, not determined. The percentage of 16S rRNA gene
- sequence identity is calculated in reference to the 16S rRNA gene sequence of the novel isolate PH1209<sup>T</sup>.

Characteristic	1	2	3	4	5	6	7
Temperature range for growth (°C) [optimum]	33-65 [60]	30-55[40]	37-68 [53]	50-70	45-65 [55]	45-70	30-68
				[60]		[55]	[50]
pH range for growth	5.0-8.0	6.0-9.0	6.4-7.4	5.5-7.5	6.5-7.4	4.5-7.5	4.2-7.0
[optimum]	[6.0-6.5]	[7.0]	[6.8-7.0]	[5.5-6.0]	[6.9-7.0]	[5.5]	[5.2]
